downloadmp3lagudegungsunda39 downloadmp3lagudegungsunda39 Q: Possible identity of the  
'bundle of dominos' force The 'bundle of dominos' is a model of friction that takes into account the  
energy needed to overcome friction between two connected rigid bodies. The model is derived from  
the expression for the work  $W = \int \mathbf{F} \cdot d\mathbf{x}$  where  $\mathbf{F}$  is the  
internal force between two connected rigid bodies that are in contact. A simplified form of the  
original model is as follows: The 'bundle of dominos' model is supposed to be applicable to the  
propagation of crack, explosion, wave propagation and avalanche. Is there any identity for the  
internal force or some other similar model that might model the 'bundle of dominos'? A: This is a  
variant of the "bundle of force chains" idea used in the modeling of stress propagation in a material.  
For brittle materials, what we call fracture propagation is a mechanism of propagation where  
material breaks all at once in a concentrated region, called a "shear crack". At the critical state of  
shear crack, the shear force drops to zero, but in the meantime the stress can reach a critical value  
so that the stress field shows a significant gradient. It was found that the gradient of the stress field  
at the crack tip exhibits an exponential shape, but the exponent of the stress field depends on the  
material being brittle or ductile. In the "bundle of force chains" idea, the force chains are f988f36e3a
